Objective C static code analysis: Using weak hashing algorithms is security-sensitive

2-3 minutes

Cryptographic hash algorithms such as MD2, MD4, MD5, MD6, HAVAL-128, HMAC-MD5, DSA (which uses SHA-1), RIPEMD, RIPEMD-128, RIPEMD-160, HMACRIPEMD160 and SHA-1 are no longer considered secure, because it is possible to have `collisions` (little computational effort is enough to find two or more different inputs that produce the same hash).

Ask Yourself Whether

The hashed value is used in a security context like:

- User-password storage.

- Security token generation (used to confirm e-mail when registering on a website, reset password, etc …).

- To compute some message integrity.

There is a risk if you answered yes to any of those questions.

Recommended Secure Coding Practices

Safer alternatives, such as SHA-256, SHA-512, SHA-3 are recommended, and for password hashing, it's even better to use algorithms that do not compute too "quickly", like `bcrypt`, `scrypt`, `argon2` or `pbkdf2` because it slows down `brute force attacks`.

Sensitive Code Example

```
#include <botan/hash.h>
// ...

Botan::secure_vector<uint8_t> f(std::string input){
    std::unique_ptr<Botan::HashFunction>
hash(Botan::HashFunction::create("MD5")); // Sensitive
    return hash->process(input);
}
```

Compliant Solution

```
#include <botan/hash.h>
// ...

Botan::secure_vector<uint8_t> f(std::string input){
    std::unique_ptr<Botan::HashFunction>
hash(Botan::HashFunction::create("SHA-512")); // Compliant
    return hash->process(input);
}
```
